Prepregnancy Counseling

**ABSTRACT:** The goal of prepregnancy care is to reduce the risk of adverse health effects for the woman, fetus, and neonate by working with the woman to optimize health, address modifiable risk factors, and provide education about healthy pregnancy. All those planning to initiate a pregnancy should be counseled, including heterosexual, lesbian, gay, bisexual, transgender, queer, intersex, asexual, and gender nonconforming individuals. Counseling can begin with the following question: “Would you like to become pregnant in the next year?” Prepregnancy counseling is appropriate whether the reproductive-aged patient is currently using contraception or planning pregnancy. Because health status and risk factors can change over time, prepregnancy counseling should occur several times during a woman’s reproductive lifespan, increasing her opportunity for education and potentially maximizing her reproductive and pregnancy outcomes. Many chronic medical conditions such as diabetes, hypertension, psychiatric illness, and thyroid disease have implications for pregnancy outcomes and should be optimally managed before pregnancy. Counseling patients about optimal intervals between pregnancies may be helpful to reduce future complications. Assessment of the need for sexually transmitted infection screening should be performed at the time of prepregnancy counseling. Women who present for prepregnancy counseling should be offered screening for the same genetic conditions as recommended for pregnant women. All patients should be routinely asked about their use of alcohol, nicotine products, and drugs, including prescription opioids and other medications used for nonmedical reasons. Screening for intimate partner violence should occur during prepregnancy counseling. Female prepregnancy folic acid supplementation should be encouraged to reduce the risk of neural tube defects.

**Recommendations and Conclusions**

The American College of Obstetricians and Gynecologists (ACOG) and the American Society for Reproductive Medicine (ASRM) make the following recommendations and conclusions:

- Any patient encounter with nonpregnant women or men with reproductive potential (eg, not post-hysterectomy or poststerilization) is an opportunity to counsel about wellness and healthy habits, which may improve reproductive and obstetric outcomes should they choose to reproduce.
- Counseling can begin with the following question: “Would you like to become pregnant in the next year?”
- The goal of prepregnancy care is to reduce the risk of adverse health effects for the woman, fetus, and neonate by working with the woman to optimize health, address modifiable risk factors, and provide education about healthy pregnancy.
- Women should be counseled to seek medical care before attempting to become pregnant or as soon as they believe they are pregnant to aid in correct dating and to be monitored for any medical conditions in which treatment should be modified during pregnancy.
- Many chronic medical conditions such as diabetes, hypertension, psychiatric illness, and thyroid disease...
have implications for pregnancy outcomes and should be optimally managed before pregnancy.

- All prescription and nonprescription medications should be reviewed during prepregnancy counseling. This review also should include nutritional supplements and herbal products that patients may not consider to be medication use but could affect reproduction and pregnancy.

- Women who present for prepregnancy counseling should be offered screening for the same genetic conditions as recommended for pregnant women.

- Women of reproductive age should have their immunization status assessed annually for tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis (Tdap); measles–mumps–rubella; hepatitis B; and varicella.

- All patients should receive an annual influenza vaccination; those women who are or will be pregnant during influenza season will have additional benefits.

- Assessment of the need for sexually transmitted infection (STI) screening should be performed at the time of prepregnancy counseling.

- Patients with potential exposure to certain infectious diseases, such as the Zika virus, should be counseled regarding travel restrictions and appropriate waiting time before attempting pregnancy.

- All patients should be routinely asked about their use of alcohol, nicotine products, and drugs, including prescription opioids and other medications used for nonmedical reasons.

- Screening for intimate partner violence should occur during prepregnancy counseling.

- Female prepregnancy folic acid supplementation should be encouraged to reduce the risk of neural tube defects (NTDs).

- Patients should be screened regarding their diet and vitamin supplements to confirm they are meeting recommended daily allowances for calcium, iron, vitamin A, vitamin B₁₂, vitamin B, vitamin D, and other nutrients.

- Patients should be encouraged to try to attain a body mass index (BMI) in the normal range before attempting pregnancy, because abnormal high or low BMI is associated with infertility and maternal and fetal pregnancy complications.

Introduction
Obstetrician–gynecologists have a prime opportunity to improve maternal and fetal outcomes through prepregnancy counseling. Like a well-woman visit, the prepregnancy visit (when the patient presents to discuss a potential future pregnancy) provides an excellent opportunity to counsel patients about maintaining a healthy lifestyle and minimizing health risks (1). The goal of prepregnancy care is to reduce the risk of adverse health effects for the woman, fetus, and neonate by working with the woman to optimize health, address modifiable risk factors, and provide education about healthy pregnancy. Prepregnancy counseling should include a review of a patient’s immunizations, an assessment for immunity, and other screenings and tests, as appropriate. All those planning to initiate a pregnancy should be counseled, including heterosexual, lesbian, gay, bisexual, transgender, queer, intersex, asexual, and gender nonconforming individuals. Pregnancy complications may be reduced by appropriate identification and mitigation of risk factors, while genetic screening may allow a couple to make informed decisions regarding family planning. Management of preexisting medical conditions may be optimized during the prepregnancy period, reducing the chances of pregnancy-related complications. Additionally, understanding aspects of patients’ social context during prepregnancy counseling may identify ways to help improve prenatal care usage, including understanding barriers that patients may face when accessing health care.

Timing of Prepregnancy Counseling
Direct screening for a patient’s pregnancy intentions, as stated in the “One Key Question Initiative,” is a core component of high-quality, primary preventive care services (2). Any patient encounter with nonpregnant women or men with reproductive potential (eg, not posthysterectomy or poststerilization) is an opportunity to counsel about wellness and healthy habits, which may improve reproductive and obstetric outcomes should they choose to reproduce. Counseling can begin with the following question: “Would you like to become pregnant in the next year?” Prepregnancy counseling is appropriate whether the reproductive-aged patient is currently using contraception or planning pregnancy. Because health status and risk factors can change over time, prepregnancy counseling should occur several times during a woman’s reproductive lifespan, increasing her opportunity for education and potentially maximizing her reproductive and pregnancy outcomes. Additionally, prepregnancy counseling can be performed by the obstetrician–gynecologist of an infertile patient before referral to a reproductive endocrinologist, further streamlining patient education. The American College of Obstetricians and Gynecologists and ASRM support coverage for and access to recommended prepregnancy counseling and services as a core component of women’s health care.

Family Planning and Pregnancy Spacing
Family planning is a foundational aspect of prepregnancy counseling. Approximately 45% of the pregnancies
in the United States are unintended, and unintended pregnancy increases the risk of pregnancy complications (3). Education and enhanced awareness of the effect of age on fertility (4) and planning for family size are essential in counseling the patient who desires pregnancy. Counseling patients about optimal intervals between pregnancies may be helpful to reduce future complications. Women should be advised to avoid interpregnancy intervals shorter than 6 months and should be counseled about the risks and benefits of repeat pregnancy sooner than 18 months (5, 6). Short interpregnancy intervals also are associated with reduced vaginal birth after cesarean success for women undergoing labor after cesarean (also referred to as trial of labor after cesarean) (7). The Centers for Disease Control and Prevention’s (CDC) U.S. Medical Eligibility Criteria for Contraceptive Use and U.S. Selected Practice Recommendations for Contraceptive Use (8, 9) can be used to facilitate evidence-based contraception counseling to meet an individual patient’s family planning and pregnancy spacing needs. For infertile women planning to use assisted reproductive technology to become pregnant, a pregnancy interval less than 18 months but greater than 6 months may be advisable (10).

An ovulatory woman who is younger than 35 years who desires pregnancy and who does not have a clearly identifiable risk factor for infertility should be expeditiously evaluated if she has not become pregnant after 12 months of unprotected intercourse. A woman who is 36 years and older should be evaluated after 6 months. A comprehensive evaluation should be conducted and treatment initiated by a healthcare provider with appropriate training and expertise. For anovulatory women and those with a clearly identifiable risk factor for infertility, strong consideration should be given to evaluation and treatment upon presentation.

Referral to a fertility specialist for males and females may be considered at any point if the infertility etiology, indicated treatment, or attempted treatment failures exceed the expertise of the obstetrician–gynecologist. Monthly ovulation is likely in women with regular and predictable menses with no greater than 2–3-day variance within a range of 25–35 days. For example, a woman with cycles every 26–28 days is likely ovulatory, while a woman with cycles of 25, 34, 26, then 35 days is likely not ovulatory. Patients desiring pregnancy should be counseled that the fertile window is having sexual intercourse in the 3–4 days before ovulation and that intercourse every 1–2 days yields the highest pregnancy rates (11). Patients may inquire about ovulation predictor kits or electronic apps for fertility. These tools vary in quality, and data on their usefulness are limited (12).

Review of Medical, Surgical, and Psychiatric Histories
Many chronic medical conditions such as diabetes, hypertension, psychiatric illness, and thyroid disease have implications for pregnancy outcomes and should be optimally managed before pregnancy (Table 1). Consideration may be given to referral to a maternal–fetal medicine specialist. Data are insufficient to recommend for or against universal screening for subclinical thyroid disease; however, screening may be appropriate for patients with risk factors (eg, age greater than 30 years, morbid obesity, history of pregnancy loss, preterm delivery, or infertility) (13).

Review of Current Medications
All prescription and nonprescription medications should be reviewed during prepregnancy counseling. This review also should include nutritional supplements and herbal products that patients may not consider to be medication use but could affect reproduction and pregnancy. The pregnancy safety of each medication and supplement should be discussed. Medications with potential teratogenicity should be reviewed and the specific risks of each individual medication discussed in detail. The importance of reliable contraception should be emphasized when a patient is taking potentially teratogenic medications. For a patient who desires pregnancy, potentially teratogenic medication should be adjusted in collaboration with the prescribing health care provider before the patient discontinues contraception. The lowest effective doses of the safest medications should be used whenever it is medically reasonable to do so. For information on the effects of medications used to manage depression during pregnancy, see The Management of Depression During Pregnancy, a report jointly developed by ACOG and the American Psychiatric Association (14). Male partners should be screened for the use of androgens, such as testosterone. Androgen use is associated with azoospermia and infertility in males, which may be reversible in some cases with cessation (15, 16).

Review of Family and Genetic History
A genetic and family history of the patient and her partner should be obtained (17–20). This may include family history of genetic disorders, birth defects, mental disorders, and breast, ovarian, uterine, and colon cancer. When any genetic disease carrier status is diagnosed in one or both partners, full medical records review and genetic counseling are recommended to educate the patient on the effects of the disease and the potential options for prepregnancy and early pregnancy screening of offspring. Women who present for prepregnancy counseling should be offered screening for the same genetic conditions as recommended for pregnant women, though insurance coverage for screening may be lacking and may be a barrier for some patients. Screening in the prepregnancy period offers the additional advantages of identifying, before pregnancy, couples at risk of having children with genetic diseases and offering appropriate testing to optimize patient education, counseling, and options for achieving pregnancy. Couples at risk of having children with specific genetic...

<tbody>
<tr>
<td>Pregestational diabetes mellitus</td>
<td>Congenital anomalies and pregnancy-related complications</td>
<td>The importance of euglycemic control before and during pregnancy should be emphasized. Optimal weight management also should be discussed in the context of managing blood sugars. Consideration should be given to testing for underlying vasculopathy with retinal examination, 24-hour urine protein testing, and electrocardiography. Thyroid dysfunction is common in women with pregestational diabetes; therefore, screening for thyroid function should be performed.</td>
<td>HbA1c &lt; 6.5% (48 mmol/mol), to reduce the risk of congenital anomalies*</td>
</tr>
<tr>
<td>Chronic hypertension</td>
<td>Preeclampsia and intrauterine growth restriction</td>
<td>Assessment of the teratogenic risk of hypertensive medications should be performed. Angiotensin converting enzyme inhibitors and angiotensin receptor blockers are contraindicated in pregnancy. Consideration should be given to testing for ventricular hypertrophy, retinopathy, and renal disease for women with longstanding or uncontrolled hypertension.</td>
<td>—</td>
</tr>
<tr>
<td>Hypothyroidism (untreated)</td>
<td>Spontaneous abortion, preeclampsia, preterm birth, placental abruption, and fetal death</td>
<td>Screening based on risk factors, rather than universal screening, should be considered for patients who are planning pregnancy. Treat if thyrotropin (previously thyroid-stimulating hormone) is above the upper level of normal.</td>
<td>—</td>
</tr>
<tr>
<td>Bariatric surgery</td>
<td>A period of rapid weight loss typically occurs in the first 12–24 months postoperatively. During this period, pregnancy is less desirable because of potential effects on fetal growth.</td>
<td>Contraceptive counseling during the postoperative period is important because the risk of oral contraceptive failure in patients who have bariatric surgery with a malabsorptive component is increased. Counseling regarding the benefits of nonoral contraceptive or LARC methods is recommended.</td>
<td>—</td>
</tr>
<tr>
<td>Mood disorders</td>
<td>Impaired maternal infant bonding, risk of maternal self-harm, or neglect. Antidepressants and antipsychotic medications increase anovulation and decrease fecundability.</td>
<td>Women with established depression or anxiety should be counseled regarding the risks of these conditions in pregnancy and the risks and benefits of treatment. The risk of relapse for bipolar disorder is higher in pregnancy, thus women with this condition should establish a strategy for managing relapse while planning for a pregnancy. Women with schizophrenia should receive counseling regarding the risks of the condition on pregnancy and the importance of establishing a plan for managing the condition during pregnancy.</td>

<tr>
<td>Human immunodeficiency virus (HIV)</td>
<td>Vertical transmission</td>
<td>Women with HIV should receive prepregnancy counseling, including a discussion of interventions to reduce vertical transmission, methods for optimizing long-term health, and the few potential effects of antiretroviral medications on the fetus. Antiretroviral therapy should be instituted before pregnancy and continued during pregnancy. Medications should not be discontinued during the first trimester. Women should continue seeing their HIV health care providers. Serodiscordant couples should receive information about the risk of sexual and perinatal transmission and about safer methods for achieving pregnancy. Women at the highest risk of acquiring HIV infection (eg, a woman not infected with HIV with a male sexual partner who is known to be infected with HIV) should be considered candidates for preexposure prophylaxis. The use of daily oral preexposure prophylaxis during pregnancy and lactation for women without HIV with HIV-infected partners has had limited study; however, the drug combination of tenofovir and emtricitabine is commonly used during pregnancy and has a reassuring safety profile.</td>
<td>Viral load should be undetectable and patients should be co-managed with an HIV health care provider.</td>

diseases can be counseled about the disease inheritance and course and offered referral for potential interventions, such as preimplantation genetic testing. See Table 2 for counseling and screening recommendations.

#### Immunizations

Women of reproductive age should have their immunization status assessed annually for Tdap, measles–mumps–rubella, hepatitis B, and varicella. All patients should receive an annual influenza vaccination; those women who are or will be pregnant during influenza season will have additional benefits (21). Adult women who have never received a dose of Tdap or whose Tdap vaccination status is unknown should receive a single dose, as recommended for nonpregnant adults by the CDC. Additionally, Tdap vaccine should be given to all women during each pregnancy between 27–36 weeks regardless of prepregnancy immunization history. Human papillomavirus vaccination (HPV) and cervical cancer screening should be performed in accordance with current guidelines. The HPV vaccination currently is not recommended during pregnancy but should not be avoided or delayed because a woman may want to become pregnant or may be actively trying to become pregnant. If the HPV vaccine series is started and a patient then becomes pregnant, completion of the vaccine series should be delayed until that pregnancy is completed (22, 23). Vaccinations for rubella and varicella should be given at least 28 days before pregnancy, or in the postpartum period if not previously given. Because two doses of the varicella vaccine are recommended, and the CDC recommends that women not become pregnant for 1 month after being vaccinated, a woman who desires pregnancy should begin vaccination 2 months before attempting pregnancy (24). Some advanced-reproductive-age patients may wish to reproduce, and those age 50 years and older should also be vaccinated against herpes zoster (25). The need for other immuni-

| Table 2. Family and Genetic History Counseling and Screening Recommendations |
|---------------------------------|---------------------------------|---------------------------------|
| **Condition** | **Who to Counsel** | **Considerations** |
| Canavan disease | Carrier screening for those of Ashkenazi Jewish descent. | |
| | When only one partner is of Ashkenazi Jewish descent, that individual should be offered screening first. If it is determined that this individual is a carrier, the other partner should be offered screening.* | |
| Cystic fibrosis | All women who are considering pregnancy* | |
| Familial dysautonomia | Carrier screening for those of Ashkenazi Jewish descent. | |
| | When only one partner is of Ashkenazi Jewish descent, that individual should be offered screening first. If it is determined that this individual is a carrier, the other partner should be offered screening.* | |
| Fragile X | Any woman with a family history of fragile X-related disorders or intellectual disability suggestive of fragile X syndrome and any woman younger than the age of 40 with unexplained ovarian insufficiency.* | Women without risk factors who request fragile X screening may be tested after informed consent. |
| Hemoglobinopathies | Couples at risk of having a child with thalassemia or sickle cell disease should be offered genetic counseling to review prenatal testing and reproduction options.* | |
| Spinal muscular atrophy | All women who are considering pregnancy | |
| Tay–Sachs disease | If either member of the couple is of Ashkenazi Jewish, French-Canadian, or Cajun descent; those with a family history consistent with Tay-Sachs disease also should be offered screening.* | Biochemical testing can be altered in women who are pregnant or using oral contraceptive pills, so leukocyte testing must be used in these patients.* |

zations should be assessed during a prepregnancy visit by reviewing health, lifestyle, and occupational risks of other infections and administering required doses as indicated (26). The CDC’s Advisory Committee on Immunization Practice immunization schedules provide the most current information on immunization recommendations (27).

**Infectious Disease Screening**

Assessment of the need for STI screening should be performed at the time of prepregnancy counseling. Guidance on recommended STI screening is available from the CDC (28) and ASRM (29). Gonorrhea, chlamydial infection, syphilis, and human immunodeficiency virus (HIV) should be screened for based on age and risk factors. Counseling to reduce STI risk should be provided (26). For current guidance on hepatitis C screening for nonpregnant women, see the CDC’s recommendations (30). Those at high risk of tuberculosis should be screened and treated appropriately before pregnancy (26). Exposure to toxoplasmosis should be assessed and avoidance counseled. Much attention has been given to educational programs to reduce maternal Toxoplasma gondii infection and, thus, congenital toxoplasmosis (31). Patients with potential exposure to certain infectious diseases, such as the Zika virus, should be counseled regarding travel restrictions and appropriate waiting time before attempting pregnancy. Obstetrician–gynecologists may ask the patient about recent or upcoming travel history for herself and her partner. The CDC offers up-to-date guidance on Zika precautions (32) and other infectious diseases (33). Information and guidance on the Zika virus also is available from ACOG (34) and ASRM (35).

**Individuals with Human Immunodeficiency Virus**

All reproductive-aged patients living with HIV should receive prepregnancy counseling if considering pregnancy (36). Prepregnancy counseling should include a detailed discussion of interventions to reduce the risk of perinatal transmission, ways to optimize long-term health, and the possible effects of antiretroviral medications on the fetus. Any HIV-infected patients who are contemplating pregnancy should be counseled that they should be receiving treatment with antiretroviral therapy, with the goal of a plasma viral load suppressed to an undetectable level before achieving pregnancy. Artificial insemination is the safest way for an HIV-infected couple to become pregnant while minimizing the risk of HIV transmission to an HIV-negative partner (37). Prepregnancy administration of antiretroviral preexposure prophylaxis for HIV-uninfected partners may offer an additional tool to reduce the risk of sexual transmission (38). A non-HIV-infected woman with an HIV-infected male partner with whom she wants to achieve pregnancy should be offered a referral to a subspecialist with the requisite training and experience in infectious disease or reproductive endocrinology and infertility for counseling. Like prepregnancy counseling for non-HIV-infected women, the goals for HIV-infected women are to improve the health of the women before pregnancy and to identify risk factors for adverse maternal and fetal outcomes. Safe sex practices and avoidance of STIs should be discussed, and both partners should be screened for STIs, which should be treated if present. The choice of antiretroviral therapy in women of childbearing capacity should take into consideration the regimen’s effectiveness, the women’s hepatitis B status, the teratogenic potential of the medications, potential drug interactions, and possible maternal and fetal adverse outcomes (37). See ACOG’s Practice Bulletin No. 167, Gynecologic Care for Women and Adolescents With Human Immunodeficiency Virus, for more information.

**Substance Use Assessment**

All patients should be routinely asked about their use of alcohol, nicotine products, and drugs, including prescription opioids and other medications used for nonmedical reasons (39, 40). Adverse effects associated with smoking during pregnancy include intrauterine growth restriction, placenta previa, abruptio placenta, decreased maternal thyroid function (41, 42), preterm labor rupture of membranes (also referred to as premature rupture of membranes) (43, 44), low birth weight, perinatal mortality (41), and ectopic pregnancy (41). Children born to women who smoke during pregnancy are at an increased risk of asthma, infantile colic, and childhood obesity (45–47). Pregnancy appears to motivate women to stop smoking; 46% of prepregnancy smokers quit smoking directly before or during pregnancy (48); however, women who are unable to quit during pregnancy likely have a tobacco use disorder (49). Effective strategies for tobacco cessation should be employed, such as the 5A’s intervention model (40).

Alcohol use patterns should be determined and patients counseled that there is no safe level or type of alcohol use during pregnancy. Fetal alcohol spectrum disorders are the most severe result of prenatal drinking and are associated with central nervous system abnormalities, growth defects, and facial dysmorphism. Alcohol-related birth defects include growth deformities, facial abnormalities, central nervous system impairment, behavioral disorders, and impaired intellectual development (50). Alcohol can affect a fetus at any stage of pregnancy, and the cognitive defects and behavioral problems that result from prenatal alcohol exposure are lifelong. Brief behavioral counseling interventions can reduce the risk of alcohol-exposed pregnancies (50–52).
Marijuana is used by an estimated 2–5% of pregnant women. Several states have recently legalized marijuana for recreational use or medicinal purposes. Marijuana may have harmful effects on reproduction and the effect of smoking marijuana during pregnancy may be as harmful as tobacco (53). Patients who are contemplating pregnancy should be encouraged to discontinue marijuana use. Patients contemplating pregnancy should be screened for opioid use and opioid use disorder. See ACOG Committee Opinion No. 711, Opioid Use and Opioid Use Disorder in Pregnancy, for validated screening tools, such as questionnaires, including 4Ps, NIDA Quick Screen, and CRAFFT (for women 26 years or younger) (39).

**Exposure to Violence, Intimate Partner Violence, and Reproductive and Sexual Coercion**

More than one in three women in the United States have experienced rape, physical violence, or stalking by an intimate partner in their lifetime (54). Screening for intimate partner violence should occur during preconception counseling. The discussion regarding intimate partner violence should be framed by indicating that all patients in the practice are screened. Assurances of privacy and confidentiality are important components of intimate partner violence screening; however, some state laws place mandatory reporting requirements on health care providers for certain types of injuries or disclosures and for certain groups of patients. Therefore, it also is important to inform patients about what it is necessary, under state laws, for physicians to disclose to authorities. Sample questions to begin the conversation are provided in ACOG Committee Opinion No. 518, Intimate Partner Violence (54). Self-administered questionnaires are as effective as a physician interview in screening for intimate partner violence and reproductive coercion. Sexual coercion includes a range of behavior that a partner may use related to sexual decision making to pressure or coerce a person to have sex without using physical force (55). The most common forms of reproductive coercion include sabotage of contraceptive methods, pregnancy coercion, and pregnancy pressure (56). If ongoing abuse is identified, assessment of the immediate safety of the patient and her family should be ascertained and community resources for victims should be provided.

**Assess Nutritional Status**

Fruits, vegetables, and daily multivitamins are good sources of antioxidants and vitamins that may assist in reproductive health for males and females. Female preconception folic acid supplementation should be encouraged to reduce the risk of NTDs. All women of reproductive age (15–45 years) should take folic acid supplementation. For average-risk women, supplementation with 400 micrograms per day is adequate. Women at increased risk of NTDs, including women with a prior pregnancy with an NTD or women with seizure disorders, should be counseled to take 4 mg of folic acid daily (57). Because of the risk of vitamin A toxicity, women who need additional folic acid should not take additional prenatal vitamins; instead, women at higher risk of NTDs should be prescribed additional folic acid supplements. Most prenatal multivitamins contain adequate amounts of folic acid for average-risk women (58). Prenatal vitamins use also is associated with a lower risk of miscarriage (59). Moderate caffeine consumption (less than 200 mg per day) does not appear to be a major contributing factor in miscarriage or preterm birth (60).

Patients should be screened regarding their diet and vitamin supplements to confirm they are meeting recommended daily allowances for calcium, iron, vitamin A, vitamin B₁₂, vitamin B₉, vitamin D, and other nutrients. The U.S. Department of Agriculture offers tools for self-dietary assessment (61), and the Office of Disease Prevention and Health Promotion offers clinical guidance (62). Recommended daily allowances are available in Guidelines for Perinatal Care, Eighth Edition, from ACOG and the American Academy of Pediatrics (63). Consumption of fish with high mercury levels should be discouraged (64, 65) and the U.S. Food and Drug Administration provides a patient resource for fish to avoid (66). Maternal listeria infection has been associated with preterm delivery and other obstetric and neonatal complications, and pregnant women should be advised to avoid eating foods with a high risk of listeria contamination. See the CDC guidance for foods to avoid (67). Patients who are at risk of eating disorders should be screened and counseled (63). Patients with malabsorptive gastrointestinal disease, bariatric surgery, or those on a vegan diet may require vitamin and mineral supplementation.

**Achieving and Maintaining a Healthy Body Weight**

Patients should be encouraged to try to attain a BMI in the normal range before attempting pregnancy because abnormal high or low BMI is associated with infertility and maternal and fetal pregnancy complications (68). The reproductive risks of obesity include, but are not limited to, infertility, miscarriage, birth defects, preterm delivery, gestational diabetes, gestational hypertension, cesarean delivery, and thromboembolic events (69, 70). Obesity also increases the risk of nonreproductive diseases, including stroke, heart disease, certain types of cancer, arthritis, high cholesterol, hypertension, and diabetes (71). Pregnant women with low BMI are at risk of having small-for-gestational-age fetuses and low-birthweight infants (72). Ideally, weight should be optimized before a woman attempts to becoming pregnant (70), although the health benefits of postponing pregnancy need to be balanced against reduced fecundity with female aging (4, 69).
Assess Exercise and Physical Activity
Regular physical exercise improves cardiovascular health, reduces obesity and associated medical comorbidities, and improves longevity. Patients should exercise moderately at least 30 minutes a day, 5 days a week, for a minimum of 150 minutes of moderate exercise per week (73). These levels of exercise are recommended prepregnancy, during pregnancy, and in postpartum women. Dietary modifications in concert with exercise produce greater weight loss than exercise alone (73). Compared with their nonathlete peers, competitive athletes require frequent and closer supervision because they tend to maintain a more strenuous training schedule throughout pregnancy and resume high-intensity postpartum training sooner. Competitive athletes should pay particular attention to avoiding hyperthermia, maintaining proper hydration, and sustaining adequate caloric intake to prevent weight loss that may adversely affect fetal growth (73).

Assess for Teratogens and Environmental and Occupational Exposures
Mounting and robust evidence suggests there are reproductive and pregnancy risks associated with environmental pollutants, workplace teratogens, and endocrine disruptors. By the time a woman presents with pregnancy, disruptions of organogenesis may have already occurred. For these reasons, prepregnancy patient history and identification of exposures are encouraged (74). If exposures are identified, patients can be educated regarding the avoidance of exposure to toxic agents and, when necessary, referred to occupational medicine programs. Exposures can occur both at home (eg, plastics with bisphenol-A, pesticides, lead paint, asbestos) and at work. Employment sectors at particular risk of potentially hazardous exposures during pregnancy include agriculture (pesticides), manufacturing (organic solvents and heavy metals), dry cleaning (solvents), and health care (biologics and radiation) (75). See the For More Information section for additional resources.

Pregnancy Dating
Women should be counseled to seek medical care before attempting to become pregnant or as soon as they believe they are pregnant to aid in correct dating and to be monitored for any medical conditions in which treatment should be modified during pregnancy. Correct first-trimester pregnancy dating provides value in managing potential subsequent pregnancy complications and indications for delivery.
