March 2016

Dear Colleague:

Evidence continues to mount regarding the benefits of breastfeeding for women and their infants. The American College of Obstetricians and Gynecologists (the College) recommends exclusive breastfeeding for the first 6 months of life, with continued breastfeeding as complementary foods are introduced through the infant’s first year of life, or longer if mutually desired by the woman and her infant. However, the rate of breastfeeding in the United States is only 49% at 6 months and 27% at 12 months, which is well below the Healthy People 2020 target rates of 60.6% and 34.1%, respectively.

As reproductive health experts and women’s health advocates who work with a variety of obstetric and pediatric care providers, obstetrician–gynecologists are uniquely positioned to enable women to achieve their infant feeding goals. The materials in this toolkit are designed to help you do just that. The recently revised Committee Opinion No. 658 explains how obstetrician–gynecologists and other obstetric care providers can support breastfeeding women and includes educational and policy recommendations. The Physician Conversation Guide on Support for Breastfeeding will help to initiate discussions about breastfeeding with your patients early in pregnancy or prenatal care. Breastfeeding Coding is conveniently located on the back of the card. If your patient has questions about breastfeeding, please give her a sheet from Breastfeeding: Frequently Asked Questions. Also enclosed is a breastfeeding infographic poster to hang in your office and spur conversations.

The College’s Breastfeeding Expert Work Group was instrumental in the development of this toolkit. Founded in February 2014, the Expert Work Group assists the College, specifically the Committee on Obstetric Practice in addition to other committees as appropriate, by providing expertise in breastfeeding medicine and developing and promoting breastfeeding tools and initiatives for obstetrician–gynecologists and other obstetric care providers and patients at all levels of the community. For further information on the College’s Breastfeeding Expert Work Group, breastfeeding guidance, and patient education, refer to our resources flyer and www.acog.org/breastfeeding. If you have additional questions, please e-mail us at breastfeeding@acog.org or call 800-410-ACOG (2264). If you would like to order supplementary materials, please visit us at sales.acog.org.

We hope the enclosed materials will be helpful to you, your practice team, and your patients. Thank you for your time and for joining our efforts in supporting women in achieving their breastfeeding goals.

Best,

Christopher M. Zahn, MD
Vice President, Practice Activities

Lauren Hanley, MD, IBCLC, FACOG
Chair, Breastfeeding Expert Work Group
ACOG COMMITTEE OPINION

Number 756

(Replaces Committee Opinion No 658, February 2016)

Breastfeeding Expert Work Group
Committee on Obstetric Practice

This Committee Opinion was developed by the American College of Obstetricians and Gynecologists’ Breastfeeding Expert Work Group and the Committee on Obstetric Practice in collaboration with work group members Susan D. Crowe, MD and Lauren E. Hanley, MD, IBCLC.

Optimizing Support for Breastfeeding as Part of Obstetric Practice

ABSTRACT: As reproductive health experts and advocates for women’s health who work in conjunction with other obstetric and pediatric health care providers, obstetrician–gynecologists are uniquely positioned to enable women to achieve their infant feeding goals. Maternity care policies and practices that support breastfeeding are improving nationally; however, more work is needed to ensure all women receive optimal breastfeeding support during prenatal care, during their maternity stay, and after the birth occurs. Enabling women to breastfeed is a public health priority because, on a population level, interruption of lactation is associated with adverse health outcomes for the woman and her child, including higher maternal risks of breast cancer, ovarian cancer, diabetes, hypertension, and heart disease, and greater infant risks of infectious disease, sudden infant death syndrome, and metabolic disease. Contraindications to breastfeeding are few. Most medications and vaccinations are safe for use during breastfeeding, with few exceptions. Breastfeeding confers medical, economic, societal, and environmental advantages; however, each woman is uniquely qualified to make an informed decision surrounding infant feeding. Obstetrician–gynecologists and other obstetric care providers should discuss the medical and nonmedical benefits of breastfeeding with women and families. Because lactation is an integral part of reproductive physiology, all obstetrician–gynecologists and other obstetric care providers should develop and maintain skills in anticipatory guidance, support for normal breastfeeding physiology, and management of common complications of lactation. Obstetrician–gynecologists and other obstetric care providers should support women and encourage policies that enable women to integrate breastfeeding into their daily lives and in the workplace. This Committee Opinion has been revised to include additional guidance for obstetrician–gynecologists and other obstetric care providers to better enable women in unique circumstances to achieve their breastfeeding goals.

Recommendations

The American College of Obstetricians and Gynecologists makes the following recommendations:

Education

- Clinical management of lactation is a core component of reproductive health care.
- Because lactation is an integral part of reproductive physiology, all obstetrician–gynecologists and other obstetric care providers should develop and maintain skills in anticipatory guidance, support for normal breastfeeding physiology, and management of common complications of lactation.

Support for Breastfeeding Women

- Women are strongly encouraged to breastfeed and the American College of Obstetricians and Gynecologists supports each woman’s right to breastfeed. Exclusive breastfeeding is recommended for the first 6 months of life, with continued breastfeeding as complementary foods are introduced during the infant’s first year of life, or longer, as mutually desired by the woman and her infant.
• The advice and encouragement of the obstetrician–gynecologist and other obstetric care providers are critical in assisting women to make an informed infant feeding decision and should be free from coercion, pressure, or undue influence.

• Obstetrician–gynecologists and other obstetric care providers should support each woman’s informed decision about whether to initiate or continue breastfeeding, recognizing that she is uniquely qualified to decide whether exclusive breastfeeding, mixed feeding, or formula feeding is optimal for her and her infant.

• When taking an obstetric history, obstetrician–gynecologists and other obstetric care providers should specifically ask about any breast surgeries, prior breastfeeding duration, and any previous breastfeeding difficulties.

• Breastfeeding is an option for women who have undergone double mastectomy and reconstruction by feeding with a supplemental feeding tube device at the breast.

• Women who experience breastfeeding difficulties are at higher risk of postpartum depression and should be screened, treated, and referred appropriately.

• Most medications and vaccinations are safe for use during breastfeeding.

• Obstetrician–gynecologists and other health care providers should consult lactation pharmacology resources for up-to-date information on individual medications because inappropriate advice often can lead women to discontinue breastfeeding unnecessarily.

• Obstetrician–gynecologists and other obstetric care providers should support women who have given birth to preterm and other vulnerable infants to establish a full supply of milk by providing anticipatory guidance and working with hospital staff to facilitate early, frequent milk expression starting within 1 hour of delivery, if possible.

• Policies that protect the right of a woman and her child to breastfeed in public and that accommodate milk expression, such as insurance coverage for breast pumps, paid maternity leave, on-site child-care, break time for expressing milk, and a clean, private location for expressing milk, are essential to sustaining breastfeeding.

Introduction

Although most women in the United States initiate breastfeeding, more than one half wean earlier than they desire (1). In addition, substantial disparities persist in initiation and duration of breastfeeding that affect population health (2). For example, in a sample of infants born between 2010 and 2013, there was a 17.2% difference in the rate of initiation among black and white women in the United States. Furthermore, there was a 7.8 percentage point difference in 6-month exclusive breastfeeding rates and a 13.7 percentage point difference in any breastfeeding at 12 months (3). Maternity care policies and practices that support breastfeeding are improving nationally; however, more work is needed to ensure all women receive optimal breastfeeding support during prenatal care, during their maternity stay, and after the birth occurs (4). As reproductive health experts and advocates for women’s health who work in conjunction with other obstetric and pediatric health care providers, obstetrician–gynecologists are uniquely positioned to enable women to achieve their infant feeding goals. This Committee Opinion has been revised to include additional guidance for obstetrician–gynecologists and other obstetric care providers to enable women in unique circumstances achieve their breastfeeding goals.

Benefits of Breastfeeding

Clinical management of lactation is a core component of reproductive health care. However, education surrounding lactation is often lacking in graduate and postgraduate medical education (5). Enabling women to breastfeed is a public health priority because, on a population level, interruption of lactation is associated with adverse health outcomes for the woman and her child, including higher maternal risks of breast cancer, ovarian cancer, diabetes, hypertension, and heart disease, and greater infant risks of infectious disease, sudden infant death syndrome, and metabolic disease (2, 6, 7).

Although lactation is the physiologic norm, cultural norms for infant feeding have changed dramatically in the past century. In 1971, only 24.7% of women left the hospital breastfeeding. Since then, breastfeeding initiation rates have progressively increased. In 2014, 82.5% of women in the United States initiated breastfeeding, 55.3% were breastfeeding at 6 months, and 33.7% were breastfeeding at 1 year after giving birth (8) (Table 1).
Breastfeeding confers medical, economic, societal, and environmental advantages; however, each woman is uniquely qualified to make an informed decision surrounding infant feeding. Obstetrician-gynecologists and other obstetric care providers should discuss the medical and nonmedical benefits of breastfeeding with women and families, (9) because engaging and educating fathers and significant others have been shown to improve breastfeeding success (10). Contraindications to breastfeeding are few and include those women who have an infant with galactosemia, are infected with human immunodeficiency virus (HIV) or human T-cell lymphotropic virus type I or type II, and have active untreated tuberculosis or varicella or active herpes simplex virus lesions on the nipple. Most medications and vaccinations are safe for use during breastfeeding, with few exceptions.

Use of medically indicated drugs or treatment for substance use disorders may not be a contraindication to breastfeeding. For example, women on stable doses of methadone or buprenorphine, who are not using illicit drugs, and who have no other contraindications, should be encouraged to breastfeed (11–13). There are insufficient data to evaluate the effects of marijuana use on infants during lactation. In the absence of data, marijuana use is discouraged (14). As the number of states legalizing and decriminalizing marijuana use increases, screening and counseling women about medicinal and recreational marijuana use during pregnancy and lactation is important and should not be overlooked. More details on marijuana use and lactation can be found in Committee Opinion No. 722, Marijuana Use During Pregnancy and Lactation (14).

**The Role of Obstetrician-Gynecologists and Other Obstetric Care Providers in Supporting Breastfeeding**

The American College of Obstetricians and Gynecologists strongly encourages women to breastfeed and supports each woman’s right to breastfeed. The American College of Obstetricians and Gynecologists recommends exclusive breastfeeding for the first 6 months of life, with continued breastfeeding as complementary foods are introduced during the infant’s first year of life, or longer, as mutually desired by the woman and her infant. This recommendation is consistent with those of other medical and nursing organizations, such as the American Academy of Pediatrics (7) and the Association of Women’s Health, Obstetric and Neonatal Nurses (15). The American College of Obstetricians and Gynecologists additionally supports public health and policy efforts to enable more women to breastfeed, including Healthy People 2020 targets for increasing worksite lactation programs, reducing formula supplementation of breastfed infants in the first 2 days of life, and increasing the proportion of births that occur in facilities that

| Table 1. Healthy People 2020 Goals for Breastfeeding |
|----------------------------------|------------------|------------------|
| **Increase the proportion of infants who are breastfed at the following stages:** | **Healthy People Goals (%)** | **Current Data U.S. National** | **Non-Hispanic Black** |
| Ever breastfed | 81.9 | 82.5±1.1* | 68.0±3.5 |

| Reduce the proportion of breastfed newborns who receive formula supplementation within the first 2 days of life | 14.2 | 15.5±1.0* | N/A |
| Increase the proportion of live births that occur in facilities that provide recommended care for lactating women and their newborns | 81 | 7.79|5 | N/A |

2Offer onsite lactation/mother’s room, defined as a separate room that goes above and beyond The Patient Protection and Affordable Care Act law, which requires that employees be “shielded from view” and “free from intrusion” during their break. Six percent offer lactation support services.

provide recommended care for lactating women and their infants (Table 1).

Because lactation is an integral part of reproductive physiology, all obstetrician–gynecologists and other obstetric care providers should develop and maintain skills in anticipatory guidance, support for normal breastfeeding physiology, and management of common complications of lactation. Obstetrician–gynecologists and other obstetric care providers should be in the forefront of policy efforts to enable women to breastfeed, whether through individual patient education, change in hospital practices, community efforts, or supportive legislation.

Obstetrician–gynecologists can play an active role in breastfeeding support by helping to ensure that their office practice setting aligns with these goals. The following practices are evidence-based options that obstetricians can implement to optimize the office setting: a written breastfeeding policy to facilitate support for breastfeeding patients and employees, providing information to patients about infant feeding that is free of artificial infant formula advertising, displaying posters and pamphlets with images of women breastfeeding that reflect the diversity of the population, and partnering with regional breastfeeding support services where patients can be referred for additional breastfeeding support after delivery (16–18).

**Prenatal Care**

The advice and encouragement of the obstetrician–gynecologist and other obstetric care providers are critical in assisting women to make an informed infant feeding decision and should be free from coercion, pressure, or undue influence (19). Women and families should receive noncommercial, accurate, and unbiased information so that they can make informed decisions about their health care (20). Obstetric care providers should be aware that personal experiences with infant feeding may affect their counseling. In addition, pervasive direct-to-consumer marketing of infant formula adversely affects patient and health care provider perception of the risks and benefits of breastfeeding.

Beginning conversations about lactation early in prenatal care by asking the patient and her family, “What have you heard about breastfeeding?” sets the stage for a patient-centered discussion. When taking an obstetric history, obstetrician–gynecologists and other obstetric care providers should specifically ask about any breast surgeries, prior breastfeeding duration, and any previous breastfeeding difficulties. Prior problems leading to earlier-than-desired weaning should be discussed, anticipatory guidance should be provided, and appropriate lactation support resources should be identified. The breast examination can identify surgical scars indicating prior surgery, as well as widely spaced, tubular breasts that may indicate insufficient glandular tissue (6). A breast assessment and breastfeeding history should be obtained as part of prenatal care, and identified concerns and risk factors for breastfeeding difficulties should be discussed with the woman and communicated to the infant’s health care provider, either directly or as part of shared records. A woman with a history of breast surgery usually can successfully breastfeed with the supervision of a health care provider to watch for any milk supply challenges or other anatomic issues related to the procedure. Of particular concern is a history of breast reduction, extensive wide local excision or multiple biopsies because these procedures can affect the ability to produce a full milk supply or permit normal anatomic drainage through the ducts, or both. Obstetrician–gynecologists and other obstetric care providers should engage the patient’s partner and other family members in discussions about infant feeding and address any questions and concerns. This patient-centered approach allows the health care provider, the patient, and her family to anticipate challenges, develop strategies to address them, and collaborate to develop a feeding plan that is compatible with the woman’s and family’s goals. Obstetrician–gynecologists and other obstetric care providers should support each woman’s informed decision about whether to initiate or continue breastfeeding, recognizing that she is uniquely qualified to decide whether exclusive breastfeeding, mixed feeding, or formula feeding is optimal for her and her infant.

Breast cancer is the most common cancer in women worldwide (21). The range of treatment options for breast cancer is wide and many of these women will go on to have children. Women who undergo lumpectomy and radiation may opt to breastfeed. The volume of milk produced after breast radiation is decreased. In addition, breast milk from an irradiated breast can have a higher sodium concentration and lower fat concentration. Infants will sometimes reject the milk from an irradiated breast or show strong preference for the nonirradiated breast, or both (22). A full milk supply may develop in the nonirradiated breast, however, counseling about nipple soreness and complications is prudent. Breastfeeding is an option for women who have undergone double mastectomy and reconstruction by feeding with a supplemental feeding tube device at the breast (23). This device has a container, often a syringe, that has a small tube attached that can be held or taped to the woman’s breast. When the infant latches, the milk from the container is drawn into the infant’s mouth through this tube. These women can still participate in skin-to-skin contact and should be offered alternative approaches to feeding their infants if desired. Some women in this population may choose to use donor milk if it is available. It is important to support these women and provide resources for them, including referral to lactation specialists who have experience in breastfeeding after a breast cancer diagnosis. There are specific support groups addressing these concerns (24).
As breastfeeding rates continue to increase in the United States, more than 33% of infants are breastfeeding at 12 months and beyond (8). Thus, the topics of lactation during pregnancy and tandem nursing (when an older child and newborn are both nursing) are becoming even more relevant to the obstetrician–gynecologist than in the past. Many nursing women may notice nipple soreness or a decrease in milk supply when they become pregnant, or both. Therefore, these symptoms should trigger pregnancy testing. A review of the limited literature available suggests that there is no increase in spontaneous abortion and preterm birth among low risk women who are breastfeeding during pregnancy, and most infants will wean from breastfeeding during the first or second trimester of the woman’s subsequent pregnancy. There is an increased risk of anemia in women who breastfeed while pregnant, and they can expect their milk supply to diminish. They also can expect to transition to colostrum during later parts of pregnancy. Tandem nursing has not been consistently associated with diminished infant growth, with some studies showing less and others showing more growth. More data are needed to fully understand the effect of breastfeeding during pregnancy in developed countries (25).

**Intrapartum Care**

Maternity care practices affect breastfeeding outcomes. The World Health Organization’s “Ten Steps to Successful Breastfeeding” (Ten Steps) is an evidence-based set of health care practices that support breastfeeding physiology, including early skin-to-skin care, enabling rooming-in, and feeding on demand (see Box 1) (2). In a systematic review of randomized controlled trials, skin-to-skin care in the first hour of life increased breastfeeding duration by a mean of 64 days (95% CI, −37.96 to 89.50) (26). Rooming-in enables women to learn and respond to infant cues and facilitates early breastfeeding. It is important to communicate the rationale for rooming-in to families during prenatal care and during the maternity care stay. A woman’s clinical situation, fatigue, or a specific request for alternative arrangements may necessitate different rooming options. The Ten Steps should be integrated into maternity care to increase the likelihood that a woman will initiate and sustain breastfeeding and achieve her personal breastfeeding goals (27). Cesarean birth is associated with lower breastfeeding rates, and women who undergo cesarean delivery may need extra support to establish and sustain breastfeeding. Skin-to-skin contact is feasible in the operating room and is associated with reduced need for formula supplementation (28).

As hospitals are making progress towards providing skin-to-skin care and rooming-in, which facilitate breastfeeding initiation, it is important that infants are adequately supervised to ensure safety, prevent falls, and prevent sudden unexpected postnatal collapse.

**Box 1. Ten Hospital Practices to Encourage and Support Breastfeeding**

1. Have a written breastfeeding policy that is routinely communicated to all health care staff.
2. Train all health care staff in the skills necessary to implement this policy.
3. Inform all pregnant women about the benefits and management of breastfeeding.
4. Help women initiate breastfeeding within 1 hour of birth.
5. Show women how to breastfeed and how to maintain lactation, even if they are separated from their newborns.
6. Give newborns no food or drink other than breast milk, unless medically indicated.
7. Practice rooming-in—allow mothers and newborns to remain together 24 hours a day.
8. Encourage breastfeeding on demand.
9. Give no pacifiers or artificial nipples to breastfeeding infants.
10. Foster the establishment of breastfeeding support groups and refer to them on discharge from the hospital or birth center.

*The 1994 report of the Healthy Mothers, Health Babies National Coalition Expert Work Group recommended that the UNICEF–WHO Baby Friendly Hospital Initiative be adapted for use in the United States as the United States Breastfeeding Health Initiative, using the adapted 10 steps above.

*The American Academy of Pediatrics endorsed the UNICEF–WHO Ten Steps to Successful Breastfeeding but does not support a categorical ban on pacifiers because of their role in reducing the risk of sudden infant death syndrome and their analgesic benefit during painful procedures when breastfeeding cannot provide the analgesia.

Particular attention is required for breastfeeding dyads when the woman is using opioid analgesia. Practicing a standardized approach to infant monitoring, which includes optimal infant positioning and observation, is vitally important in order to avoid adverse events (see Box 2) (29). The American College of Obstetricians and Gynecologists’ Committee Opinion No. 742 and Committee Opinion No. 711 include further discussion about opioid use and breastfeeding (11, 30).

Healthy People 2020 and the Joint Commission have targeted unnecessary formula supplementation as a barrier to establishing breastfeeding, and maternity care providers can provide anticipatory guidance for families regarding the rationale for avoiding early introduction of formula. Distribution of formula marketing packs reduces breastfeeding initiation and duration (31) and implies that formula is a recommended feeding method.
Moreover, provision of samples implies the health care provider’s endorsement of a specific brand, which encourages families to purchase more expensive brand-name products, rather than generic equivalents (32). Such marketing should not occur in inpatient or outpatient health care settings.

The adolescent birth rate continues to decrease in the United States, but it remains the highest in the developed world. Most adolescent mothers would like to breastfeed, but they face unique challenges particular to their age. This cohort breastfeeds less exclusively and for shorter duration than their older counterparts when dividing women by age 20 years or younger (33). When adolescents are exposed to more components of the Ten Steps, they also tend to breastfeed longer and more exclusively. Thus, Ten Steps care is a practice that supports females of all ages and should not be denied to adolescents. Adolescent mothers are a vulnerable population in whom the health effects of breastfeeding could be particularly beneficial (34).

Overall, the preterm birth rate in the United States is currently 9.8% and black women have a premature rate of 13.3%, which is 49% higher than the preterm birth rate among all other women (35). The American Academy of Pediatrics states that all preterm infants should receive human milk. If a woman’s own milk is not available, pasteurized donor human milk is the next best alternative (36). When fed human milk, this fragile group of infants has a lower risk of necrotizing enterocolitis, retinopathy of prematurity, late onset sepsis, and lower readmission rates in the first year of life (37, 38). Sharing this information with women who have given birth to preterm infants and who intend to formula feed can increase breastfeeding initiation without increasing maternal anxiety (39).

Obstetrician–gynecologists and other obstetric care providers should collaborate with the pediatric care provider to share this information as soon as a preterm birth is anticipated because initiation of milk expression within 6 hours of birth is associated with improved milk production (40). Obstetrician–gynecologists and other obstetric care providers should support women who have given birth to preterm and other vulnerable infants to establish a full supply of milk by providing anticipatory guidance and working with hospital staff to facilitate early, frequent milk expression starting within 1 hour of delivery, if possible (41, 42). It is important to recognize and support this vulnerable group of mother–infant dyads because these women have particular challenges to initiate and maintain milk supply.

### Clinical Management of the Breastfeeding Dyad

The offices of obstetrician–gynecologists and other obstetric care providers should be a resource for breastfeeding assistance throughout the entire breastfeeding relationship. Breastfeeding is a two-person activity, and evaluation of breastfeeding problems requires assessment of the woman and her infant, as well as the active engagement and support of her partner, extended family, or other identified support. Management of issues such as pain, perceived or actual low milk supply, breast infections, and maternal medication safety should, therefore, be coordinated with the infant’s health care provider as appropriate. Office staff should be prepared to triage common breastfeeding concerns and to refer women, as needed, to a certified lactation professional in the community, such as an International Board Certified Lactation Consultant or other lactation provider. Embedding lactation professionals within the offices of an obstetrician–gynecologist or other obstetric care provider may be feasible with coverage of lactation services included as preventive care under the Affordable Care Act (43). The American College of Obstetricians and Gynecologists encourages each health care provider to learn his or her own community resources to best support patients. In addition, screening patients for Women, Infants, and Children eligibility during prenatal care is an important way to help provide breastfeeding and nutrition support to many women and families. This type of collaborative care model helps enable women to achieve their feeding goals (44).

Most medications are safe for use during breastfeeding. Obstetrician–gynecologists and other health care providers should consult lactation pharmacology resources for up-to-date information on individual medications (12) because inappropriate advice often can lead women to discontinue breastfeeding unnecessarily. LactMed is a free resource updated monthly from the National Institutes of Health National Library of Medicine and available online or as an app compatible with

Pain is a common cause of premature weaning. In one study of more than 1,300 women who stopped breastfeeding in the first month, approximately two out of three cited pain or sore, cracked, or bleeding nipples as an important reason (50). The differential diagnosis of nipple or breast pain is broad and complex. The support of the breastfeeding woman with pain requires time and knowledge. If the symptoms, history, and physical examination do not confer a diagnosis, additional evaluation and milk removal is the most effective strategy to increase milk production. There is limited evidence for medications and herbal galactagogues to increase milk supply (49).

Disrupted lactation is common, with one in eight women reporting early, undesired cessation of breastfeeding because of multiple problems with pain, low milk supply, or the infant being unable to latch on to the breast (48). Obstetric care providers should collaborate with certified lactation professionals and the infant’s health care provider to evaluate and manage breastfeeding problems. Even with comprehensive support, some mother–infant dyads are unable to establish sustained, exclusive breastfeeding. Women who are not able to achieve their breastfeeding intentions report considerable distress, and obstetrician–gynecologists and other health care providers should validate each woman’s efforts and experience. Women who experience breastfeeding difficulties are at higher risk of postpartum depression and should be screened, treated, and referred appropriately (6).

Contraception is an important topic for all women, and comprehensive discussion of methods should not be delayed for breastfeeding women. Although breastfeeding without introducing any complementary solids or formula will in most cases prevent ovulation and, thus, pregnancy for up to 6 months after giving birth, it will do so only when women are fully or nearly fully breastfeeding and there is continued amenorrhea. Contraceptive options should be explained in detail and include nonhormonal methods (copper intrauterine devices, condoms, diaphragms, lactational amenorrhea method), and hormonal methods (levonorgestrel intrauterine device, etonogestrel implant, medroxyprogesterone acetate injection, progestin-only pills, and combined hormonal contraceptive pills) (52). The American College of Obstetricians and Gynecologists endorses the Centers for Disease Control and Prevention’s evidence-based medical eligibility criteria for contraceptive use, which states that, for breastfeeding and nonbreastfeeding women, the advantages of progestin-only pills, injectable contraception, contraceptive implant, and intrauterine devices outweigh the risks for use any time in the postpartum period, including immediately after birth. Because of an increased risk of venous thromboembolism, the advantages of combined hormonal contraceptives, however, do not outweigh the risks for women until 1 month after giving birth (53). The Centers for Disease Control and Prevention and the World Health Organization diverge on recommendations for combined hormonal contraceptives beyond the early postpartum period; according to the World Health Organization, primarily breastfeeding women generally should not use combined hormonal contraceptives from 6 weeks through 6 months after giving birth (54).

Theoretical concerns exist that exogenous progesterone could prevent the onset of milk production because progesterone withdrawal after delivery of the placenta is thought to trigger onset of lactogenesis (48). Women considering immediate postpartum progesterone-only contraception should be counseled about the theoretical risk of reduced duration of breastfeeding and about the preponderance of evidence that has not shown a negative effect on actual breastfeeding outcomes (55–57). Obstetric care providers should discuss any concerns within the context of each woman’s desire to breastfeed and her risk of unplanned pregnancy, so that she can make an autonomous and informed decision.

Breastfeeding in the Community

Obstetrician–gynecologists and other obstetric care providers should support women and encourage policies that enable women to integrate breastfeeding into their daily lives and in the workplace. Before discharge from the maternity center, women should be provided with contact information for community-based lactation support. Maintaining milk supply depends largely on frequency of milk removal through breastfeeding and through expressing milk (breast pumping or manual expression) when the woman and her infant are separated. Policies that protect the right of a woman and her child to breastfeed in public and that accommodate milk
expression, such as insurance coverage for breast pumps, paid maternity leave (58), on-site childcare, break time for expressing milk, and a clean, private location for expressing milk (59), are essential to sustaining breastfeeding. Obstetric care provider offices and hospitals can set an example through supportive policies for lactating staff, accommodations for nursing patients, awareness and educational materials, and staff training (15, 16). Laws vary by state, and health care providers should be aware of their state and local laws to inform and empower patients to feel comfortable breastfeeding in public and supported in achieving their breastfeeding goals (see the For More Information section for more information on state and local laws) (2).

Breastfeeding: Frequently Asked Questions

How does breastfeeding my baby benefit me?

Breastfeeding is good for you for the following reasons:

- Breastfeeding burns as many as 500 extra calories each day, which may make it easier to lose the weight you gained during pregnancy.
- Women who breastfeed longer have lower rates of type 2 diabetes, high blood pressure, and heart disease.
- Women who breastfeed have lower rates of breast cancer and ovarian cancer.
- Breastfeeding releases oxytocin, a hormone that causes the uterus to contract. This helps the uterus return to its normal size more quickly and may decrease the amount of bleeding you have after giving birth.

How does breastfeeding benefit my baby?

Breastfeeding benefits your baby in the following ways:

- Breast milk has the right amount of fat, sugar, water, protein, and minerals needed for a baby’s growth and development. As your baby grows, your breast milk changes to adapt to the baby’s changing nutritional needs.
- Breast milk is easier to digest than formula.
- Breast milk contains antibodies that protect infants from ear infections, diarrhea, respiratory illnesses, and allergies.
- Breastfed infants have a lower risk of sudden infant death syndrome. Any amount of breastfeeding appears to help lower this risk.
- If your baby is born preterm, breast milk can help reduce the risk of many of the short-term and long-term health problems that preterm babies face, such as necrotizing enterocolitis or other infections.

How long should I breastfeed my baby?

It is recommended that babies exclusively breastfeed for the first 6 months of life. Exclusive breastfeeding means to feed your baby only breast milk and no other foods or liquids unless advised by the baby’s doctor. Breastfeeding should continue as new foods are introduced through the baby’s first year. You can keep breastfeeding after the first year as long as you and your baby want to continue. You can use a breast pump to express milk at work to provide milk for your baby when you are separated. This also helps to keep up your supply while you are away from your baby.

When can I begin breastfeeding?

Most healthy newborns are ready to breastfeed within the first hour after birth. Hold your baby directly against your bare skin (called “skin-to-skin” contact) right after birth. Placing your baby against your skin right after birth triggers reflexes that help your baby to attach or “latch on” to your breast.

How do I know my baby is hungry?

When babies are hungry, they will nuzzle against your breast, suck on their hands, flex their fingers and arms, and clench their fists. Crying usually is a late sign of hunger. When babies are full, they relax their arms, legs, and hands and close their eyes.

(see reverse)
How do I know my baby is getting enough milk?

Your baby’s stomach is very small, and breast milk empties from a baby’s stomach faster than formula. For these reasons, you will typically breastfeed at least 8–12 times in 24 hours during the first weeks of your baby’s life. If it has been more than 4 hours since the last feeding, you may need to wake up your baby to feed. Each nursing session typically lasts 10–45 minutes. Once your breast milk transitions from colostrum to mature milk, your baby will soak at least six diapers a day with urine and have at least three bowel movements a day. After 10 days, your baby will be back up to birth weight. Although breastfeeding works for most women, it may not work for everyone.

Who can help me with breastfeeding?

- **Peer counselors**, such as those found with La Leche League and Women, Infants, and Children (WIC), are women who have experienced breastfeeding and can help with nonmedical breastfeeding questions and support. Check with your obstetrician-gynecologist or other health care provider about resources available in your area.
- **Certified lactation counselors** can teach you what you need to know to get started with breastfeeding, and **international board-certified lactation consultants** can help you navigate problems many women face while breastfeeding.
- **Hospital nurses** can help you find a comfortable position for nursing in the days after delivery.
- Your infant’s **pediatric care provider** can help answer questions about infant nutrition and infant weight gain.
- **Obstetrician–gynecologists and other obstetric care providers** can discuss breastfeeding with you during pregnancy and can help you plan for a successful start to breastfeeding. They also can help in the hospital, at your postpartum visit, and beyond.

Resources for Patients

- American College of Obstetricians and Gynecologists [http://www.acog.org/breastfeeding](http://www.acog.org/breastfeeding)
- MotherToBaby 866-626-6847 [http://mothertobaby.org](http://mothertobaby.org)
Pertinent Medical and Surgical History: Ask about breast surgery (including reduction or augmentation and significant trauma or radiation to the chest wall), which could affect breastfeeding performance.

Medications: For chronic medications, ask what the patient knows about drug safety in lactation. Consult LactMed for long-term medications and provide her with printed resources, such as LactMed monographs or MotherToBaby fact sheets, for information on safety of medications she anticipates taking after giving birth.

Anticipatory Guidance: Begin conversations about lactation early in prenatal care using three-step counseling: 1) Ask the patient an open-ended question and listen to her response, 2) Summarize her response in your own words, and 3) Educate, addressing her concerns.

Some questions and suggestions for education:

**What have you heard about breastfeeding?**
- Health effects: Breastfeeding is different from formula feeding. Discuss benefits for the woman and the baby.
- Pain: Many women experience discomfort with latching in the early days as the baby draws the nipple and areola into its mouth. Pain lasting more than 20–30 seconds is a signal to adjust the baby’s position, sometimes simply by shifting the baby’s torso to face the woman’s body. Hospital staff will help with positioning too.
- When to feed: The baby has a fuel gauge—elbows flexed and fists near the mouth mean “empty” and arms relaxed mean “full.” One arm flexed means “I might want dessert.”
- Making enough milk: To make lots of milk, put the baby to the breast early and often. The breasts are stimulated to make more milk by having colostrum or milk removed from them. The woman will make as much milk as her baby removes. Acknowledge that although breastfeeding works for most women, it may not work for everyone.
- Nursing in public: Discuss how to nurse discreetly, and review that the woman has a legal right to breastfeed in public. Consider timing outings and using an infant sling, a breastfeeding cover, and a breastfeeding bra. Empower women to request a private space for nursing.

**What have you heard about how long to breastfeed?**
- Review recommendations for 6 months of exclusive breastfeeding, continuing for 1 year or longer if mutually desired by the woman and the baby as new foods are introduced after the first 6 months.

**How does your family or partner feel about breastfeeding?**
- Offer to consult with unsupportive family or partner.
- Concerns about sexuality: Explore the partner’s cultural values; explain the primary role of breasts as nourishment.

**What are your plans for returning to work or school in the first few months after birth?**
- Discuss opportunities for expressing milk at work or school. If there are none, the woman and her baby will adapt to more frequent nursing in off times. Express milk when at home for the next day’s supply. The Affordable Care Act requires most employers to provide breastfeeding women with breaks to express milk in a place other than a bathroom. Find out more at http://www.dol.gov/whd/nursingmothers/.

**Multiparous women: How did feeding go with your older child or children?**
- Praise the patient for any previous breastfeeding. Ask about challenges she encountered and strategies for overcoming them. Offer a prenatal consult with an International Board Certified Lactation Consultant for anticipatory guidance. If the patient formula fed, explore reasons for her decision. Ask if she has considered breastfeeding.

Breastfeeding Coding for Obstetrician–Gynecologists 2016

Commonly Used Codes for Breastfeeding

<table>
<thead>
<tr>
<th>ICD-10 Code</th>
<th>Breastfeeding Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>O91.03</td>
<td>Infection of nipple associated with lactation</td>
</tr>
<tr>
<td>O91.13</td>
<td>Abscess of breast associated with lactation</td>
</tr>
<tr>
<td>O91.23</td>
<td>Nonpurulent mastitis associated with lactation</td>
</tr>
<tr>
<td>O92.03</td>
<td>Retracted nipple associated with lactation</td>
</tr>
<tr>
<td>O92.13</td>
<td>Cracked nipple associated with lactation</td>
</tr>
<tr>
<td>O92.5</td>
<td>Suppressed lactation</td>
</tr>
<tr>
<td>O92.70</td>
<td>Unspecified disorders of lactation</td>
</tr>
<tr>
<td>O92.79</td>
<td>Other disorders of lactation</td>
</tr>
<tr>

</tr>
<tr>
<td>O92.70</td>
<td>Unspecified disorders of lactation</td>
</tr>
<tr>
<td>O92.79</td>
<td>Galactoceles (other disorders of lactation)</td>
</tr>
</tbody>
</table>
| Z39.1       | Encounter for care and examination of lactating woman (excludes encounter for conditions related to O92-)

The codes represented in this chart with an * require a 6th digit to specify trimester. The guidelines for 6th-digit requirements for this code set are as follows: 1 (first trimester), 2 (second trimester), 3 (third trimester), or 9 (unspecified trimester). The codes represented in this chart with an ^ require an additional digit as indicated with the dash (-). The guidelines for 7th-digit requirements for this code set are as follows: A (Initial Encounter), D (Subsequent Encounter), or S (Sequela).

If a feeding problem exists that requires the physician to spend an additional amount of time addressing the problem, the following codes are appropriate. This would include the obstetrician–gynecologist or other health care provider taking the woman’s history, examining her breasts and nipples, observing a feeding, and making a diagnosis and treatment plan for the woman:

Breastfeeding may make it easier to lose the weight you gained during pregnancy. Women who breastfeed longer have lower rates of type 2 diabetes and high blood pressure. Women who breastfeed have lower rates of breast cancer and ovarian cancer. Breastfeeding triggers the release of oxytocin that causes the uterus to contract and may decrease the amount of bleeding you have after giving birth.

Breast milk has the right amount of fat, sugar, water, protein, and minerals needed for a baby’s growth and development. Breast milk is easier to digest than formula, and breastfed babies have less gas, fewer feeding problems, and less constipation. Breast milk contains antibodies that protect infants from certain illnesses, such as ear infections, diarrhea, respiratory illnesses, and allergies. Breastfed infants have a lower risk of sudden infant death syndrome (SIDS). If your baby is born preterm, breast milk can help reduce the risk of many of the short-term and long-term health problems.
